Abstract

Objective: Gout is the most prevalent form of arthritis afflicting Filipinos. The diagnosis and overall management need further improvement especially among medical practitioners. Our study aims to develop evidence-based guidelines for general medical practitioners on the management of uncomplicated gout with the overall goal of improving the standard of care of patients with gouty arthritis.

Methodology: The Technical Review Committee (TRC) of the Philippine Rheumatology Association (PRA) Gout Special Interest Group (SIG) conducted a literature search relating to management issues on all phases of gout from years 1980 to 2007 using databases including Medline, Ovid, Lilacs, Cochrane Central Register of Controlled Trials (CENTRAL). The GRADE system in rating quality of evidence and strength of recommendation was used. A multidisciplinary panel voted and approved the final recommendations during an en banc meeting.

Results: Nine recommendations for the management of uncomplicated gouty arthritis were developed based on evidence from the literature and consensus among experts and key stakeholders. Concerns regarding the initiation and maintainance of urate lowering therapy, target serum uric acid levels, treatment of acute gout, lifestyle and dietary modifications, comorbidities associated with gout such as cardiovascular disease were addressed.
INTRODUCTION

Gout is the most prevalent form of arthritis among the Filipinos. The prevalence of gout is 1.6% (1), a distinctive uptrend compared to 1991 when the prevalence was 0.5% (2), and in 1997 when the prevalence was 0.13% (3). Despite known quality indicators for treatment of gout (4), there is poor adherence of physicians to these indicators (5). Interestingly, inappropriate management of gout is a frequent occurrence even with physician consultation (6).

The Philippine Rheumatology Association (PRA) sought to establish evidence-based guidelines with the goal of improving the standards of care for patients with gout. It is intended to assist medical care providers in making decisions on the care of these patients based on the best available evidence. Guidelines were specifically sought to address the following issues: to assess the role, safety and effectiveness of available therapies including colchicine, corticosteroids, allopurinol; to establish the role of non-pharmacologic measures including dietary modification, alcohol cessation, ice compress; to define the importance of addressing hyperuricemia; to address the role of other hypouricemic agents such as losartan and fenofibrate; to emphasize cardiovascular and renal co-morbidities associated with uncontrolled gout and hyperuricemia. Issues related to the diagnosis of gout and management of complicated cases of gout are not included in this guideline. The full-length text of the guidelines can soon be found on www.philippinerheumatology.org.

METHODOLOGY

The PRA Gout Steering Committee convened a technical review committee to search for and grade the available evidence related to the management of all phases of gout.
A search for studies published in English between 1980 and 2007 was done: systematic reviews, meta-analysis, randomized controlled trials (RCTs), open label trials, cohort studies on general population, and case reports on different phases of gouty arthritis. Authors of irretrievable published articles were contacted. Full articles and abstracts were appraised.

The following electronic databases used included: PUBMED, METACRAWLERS, GOOGLE SCHOLAR, OVID, MEDLINE, Cochrane Central Regions of Controlled Trials (CENTRAL), the Cochrane Library Issue 3, 2004, LILACS. All related reference lists of retrieved trials/studies were likewise hand-searched. The following search terms were used: asymptomatic hyperuricemia, hyperuricemia, allopurinol hypersensitivity, allopurinol hypersensitivity syndrome, allopurinol, metabolic syndrome, cardiovascular events (congestive heart failure, hypertension, stroke), diabetes mellitus, renovascular events (end stage renal disease), purine diet, gout/gouty arthritis, losartan, fenofibrate, colchicine, non-steroidal anti-inflammatory drugs (NSAID), selective cyclo-oxygenase 2 (COX-2) inhibitors, tophi, tophaceous gout, intra-articular/oral/systemic corticosteroid/glucocorticoid. Data abstraction was performed independently by at least 2 separate investigators. Disagreements were settled through discussions. The GRADE system (7,8) was utilized in evaluating the quality of evidence and strength of recommendation. Panel members based their recommendations on the merits of each evidence, expert opinion, and local applicability and affordability of treatment approaches.

Recommendations were then presented to a multidisciplinary panel comprised of representatives from the Department of Health, and nine other medical societies (Philippine College of Physicians, Philippine Society of Nephrology, Philippine Pharmacists Association, Philippine Heart Association, Philippine Society of Endocrinology and Metabolism, Philippine Academy of Family Physicians, Nutritionist-Dietitian Association of the Philippines, and
Philippine Academy of Rehabilitation Medicine), and a patient with gout. During an en banc meeting, nominal group technique was employed. Panel members cast their votes to finalize the recommendations.

RESULTS

Nine recommendations were defined by the panel (Table 1).

Phase 1: Asymptomatic Hyperuricemia

Hyperuricemia is defined as serum uric acid (SUA) level exceeding the limit of urate solubility in the plasma, which is 7 mg/dl (416 umol/L) in men and 6 mg/dl (357 umol/L) in pre-menopausal women. Asymptomatic hyperuricemia is defined as hyperuricemia in the absence of gouty arthritis and uric acid nephrolithiasis. The prevalence of hyperuricemia is 37.8% in males and 18% in females (1).

Hyperuricemia is a central feature of gout but does not inevitably and absolutely cause it. The development of gout seems to be directly related to the level of hyperuricemia; however, it is not absolute. The cumulative incidences of gout up to 5 years are increased in direct relation to elevated levels of SUA (9,10). Hyperuricemia is also associated with hypertension (11,12,13), obesity (12), and albuminuria in the presence of renal disease (14). One prospective study did show that allopurinol treatment may result in improvements in blood pressure and creatinine clearance but not in proteinuria; however, this study included patients with normal renal function and allopurinol dose was not specified (15). In another trial involving patients with chronic kidney disease, allopurinol treatment resulted in improvements in renal disease but without significant improvements in hypertension and proteinuria (16). Further studies are needed to confirm the benefit of allopurinol in decreasing cardiovascular and renal risks in the general population.
The relative risks (RR) for incident gout and hyperuricemia were significantly increased with intake of meat, seafood, alcohol especially beer and spirits (17-20). Low to moderate purine diet may reduce SUA and risk of gout while moderate consumption of purine-rich vegetable, low fat dairy products, low fat-yoghurt were not associated with increased risk of gout (18). High protein intake may increase risk of hyperuricemia (19).

The expert panel further recommended low impact and aerobic exercises at least 45 minutes 4 times a week, intake of at least 8 glasses of water a day, and maintenance of appropriate BMI (21).

Phase 2: Acute Gouty Arthritis

Acute gouty arthritis is defined in accordance with the 1977 American College of Rheumatology (ACR) criteria for the classification of acute attack of primary gout (22).

There is no evidence demonstrating benefit with a hierarchal order in the use of medications for acute gout. The Philippine guidelines recommend that the choice of drug for acute gouty arthritis be individualized taking into consideration drug efficacy, safety, and cost.

Studies comparing indomethacin with other NSAIDs have shown comparable efficacy in reducing pain (23-25). Etoricoxib, a selective cyclooxygenase—2 inhibitor, is also effective but with less gastrointestinal adverse events (26). “Short course oral steroids” is defined as 30 mg oral prednisone tapered off over 6 days. Corticosteroids are useful for patients who have contraindications to therapy with NSAIDs (27, 28). Parenteral corticosteroids may be used among those who cannot take oral corticosteroids. Colchicine hastens the resolution of an acute gout attack (29). However due to significant gastrointestinal toxicity, the expert panel recommends limiting colchicine to 0.5mg/tab 1 tab BID-QID. Ice compress along with corticosteroids and colchicine is also beneficial (30).
**Phases 3 and 4: Intercritical Gout and Chronic Tophaceous Gout**

**Intercritical Gout**, referred to as “interval gout”, applies to the asymptomatic periods between gouty attacks. Chronic Tophaceous Gout (CTG) occurs in untreated gouty arthritis, characterized by persistent low grade inflammation of joints with sporadic flares. Joint deformities seen are due to deposition of massive urate crystals forming visible tophi (29).

ULT is indicated in the following situations: recurrent attacks, radiographic changes, tophaceous deposits, renal insufficiency, nephrolithiases (26). Likewise, individuals with high serum urate (>13 mg/dl) even without clinical signs of gout and high renal urate excretion should be candidates for ULT to prevent uric acid nephrolithiases (31).

There is considerable data showing a direct benefit in lowering SUA on the course of gout. Fifty-six percent of patients who achieved SUA <6 mg/dl had depletion of urate crystals from their knee joints and experienced less gout flares annually compared to patients unable to achieve this target (32). In a review of 267 patients followed up for 3 years, infrequent gouty attacks were associated with reduced SUA concentrations (33). SUA levels between 4.6–6.6 mg/dl is associated with fewer gout attacks (34) and faster rate of reduction of size of tophi (35). Tophaceous deposits were persistent in 37% of those whose urate values remained >6 mg/dl (35). SUA > 6 mg/dl is associated with 59% higher chances of gout flare (32).

Lowering SUA to <6 mg/dl has likewise shown reduction of tophi size (35). A prospective study revealed an inverse relationship of SUA levels and rate of tophi reduction (32). Although “normal” ranges of SUA levels differ among, laboratory facilities across the country, due to lack of standardization, optimal SUA levels of gout patients should be kept at <6mg/dl.

Allopurinol is a xanthine oxidase inhibitor considered to be the cornerstone of the clinical management of gout and other conditions associated with hyperuricemia. It is used in both urate overproducers and underexcretors. It is the preferred urate-lowering drug in
several countries (36, 37) and is the only drug available in this class in the Philippines. It has been found to have the lowest incremental cost-effectiveness ratio (38). Despite its widespread use, there is a dearth of clinical trials addressing its long term efficacy and safety for gout. Data from randomized clinical trials showed that allopurinol given at a daily dose of 200–600 mg for 12-30 months reduced SUA levels by 3.16 to 4.8 mg/dl with consequent reduction in gout flares and resolution of tophi in some patients (39-40). Additional benefits on renal function among chronic gout patients revealed preserved or improved creatinine clearance after 12-24 months of therapy (39).

Most clinical studies advocate continuous use over intermittent use of urate-lowering therapies. SUA rise rapidly to pretreatment levels after drug discontinuation with recurrence of gout flares and tophi (41-42). One small prospective 5-year follow-up study of gout suggested intermittent therapy could be offered to patients with good SUA control (43).

Recent studies have evaluated the adjunctive benefits of fenofibrates and losartan among patients with gout. In the absence of large trials, these may be considered for the treatment of concomitant dyslipidemia and hypertension among gout patients. Other uricosuric agents (sulfinpyrazone, benzbromarone and probenecid), are not being dispensed locally. New drugs are still undergoing clinical trials. Febuxostat, an oral non-purine selective inhibitor of xanthine oxidase, as of May 2008 has been approved for use in the European Union, and is currently undergoing further evaluation in the United States by the Food and Drug Administration (FDA). PEG-uricase, a recombinant mammalian urate oxidase, also shows promise in treating gout-related hyperuricemia.

Conclusions
We have developed the first clinical practice guidelines in the Philippines for management of uncomplicated gouty arthritis based on best available evidence and best clinical practice. Nine key recommendations were extensively evaluated. Updates in management issues will be integrated as deemed necessary in the next 3 or more years.

<tbody>
<tr>
<td>1. In the general population, asymptomatic hyperuricemia should not be routinely treated with allopurinol. Well-known associated risk factors of hyperuricemia, ie. dyslipidemia, obesity, metabolic syndrome, psoriasis, malignancies, congestive heart failure, and hypertension.</td>
</tr>
</tbody>
</table>
heart failure, should foremost be addressed.

2. Lifestyle changes recommended include the following:

Adherence to animal or vegetable protein diet as well as intake of dairy products is recommended.

Avoidance of a high meat and seafood diet and alcoholic beverages most especially beer should be prescribed.

Low impact and aerobic exercise at least 45 minutes 4 times a week, intake of at least 8 glasses of water a day, and maintenance of appropriate BMI, are likewise advised.

### Phase 2: Acute Gout

3. In the absence of contraindications, ie. gastrointestinal ulcers or renal impairment, the use of colchicine, traditional non-steroidal anti-inflammatory drugs (NSAIDs), OR selective cyclo-oxygenase 2 (COX-2) inhibitors is recommended for the treatment of acute gouty arthritis.

The expert panel recommends that colchicine should not exceed 4 tablets in divided doses per day.

Prednisone, initially at 30 mg and rapidly tapered over 6 days, can be given as alternative if colchicine, traditional NSAIDs or COX-2 inhibitors are contraindicated or not tolerated by the patient.

Absence of response after a week should prompt reevaluation of the diagnosis and referral to a rheumatologist.

4. Ice compress is recommended in combination with pharmacologic agents for relief of joint pain and swelling of acute gouty arthritis.
